XDF-50
DRIVER FLOW CHART EXPLANATION

1) The following parameters are provided by the calling program:

   a) Unit (0-3)
   b) Pack (0-1)
   c) Cylinder (0-C) C = Last Cylinder #
   d) Track (0-1)
   e) Sector (0-S) S = (# Sectors/Revolution) - 1
   f) Type of Operation
   g) Memory Address
   h) Word Count

2) The driver transfers a maximum of one sector per call. The memory address and word count should be set according to the type of operation as follows:

   a) For the following operations the memory address should point to the first word of data to be transferred and the word count should be less than or equal to the number of data words per sector.

Operation Code	Operation
2	Normal Write Operation
3	Normal Read Operation
5	Normal Write Ignoring the Sector Write Protect Flag
7	Read Without Checking the Preamble

   b) For the following operation the memory address should point two words prior to the data to be transferred (if any) and the word count should be greater than or equal to 2 and less than or equal to the number of data words per sector plus 2. The words preceeding the data should contain a properly formatted preamble for the sector to be written.

Operation Code	Operation
1	Write Preamble and Data

3) The entry point to the driver is DSIO. BGSK is an internal subroutine used to select the unit and initiate seeks. A normal exit from DSIO indicates that the operation was completed without error. An error exit from either DSIO or BGSK returns an error code that indicates the error that was detected. In either case the term "exit" refers to a return to the program that called DSIO.
